# PHASE 0: INTAKE (Smelling Salts)

## Baseline Score: $^{41}/_{100}$

### The Triggering Event

The previous V13 Learning Loop (Session LL-V13-MJ-MEMORY-20260304, PRIMAL 95%) designed the Constitutional Memory System and certified it at $^{93}/_{100}$. That was the **architecture**. The architecture was then deployed across all three horizons to `timjlatimer/master-jeeves-brain` — a private GitHub repository containing 10 markdown files across 4 defense layers.

Then Tim issued a new directive — a directive that retroactively exposes a **fundamental architectural flaw** in the deployed system:

> ***"All instruments, memory, and operational protocols must be programmatic code, not markdown documentation. Markdown is only for the human-readable constitutional source files. Everything else is enforced by code."***

## The Smelling Salts Reframe

The previous Learning Loop solved the **inheritance failure** — the problem that subtasks never received Tim's directives. It designed a 4-layer defense system: Fireproof Safe (storage), Village Crier (injection), Checkpoint (verification), Watchtower (drift detection). That design was sound.

But the **implementation** committed a critical category error: **Layers 2, 3, and 4 were deployed as markdown documentation, not as executable code.**

Consider what this means:

- **INJECTION_PROTOCOL.md** (361 lines) describes *how* to inject directives into subtasks. It contains templates, examples, and rules. But it does not **execute** the injection. It is a manual that hopes someone reads it and follows the instructions.
- **VERIFICATION_GATE.md** (227 lines) describes *how* to verify subtask outputs against directives. It contains a three-step process, scan templates, and classification rules. But it does not **run** the verification. It is a checklist that hopes someone performs the checks.
- **DRIFT_DETECTION.md** (339 lines) describes *how* to detect drift across five triggers. It contains NEVER-COMPRESS rules, weekly audit templates, and recovery protocols. But it does not **detect** anything. It is a watchtower with no watchman inside.

**The Smelling Salts reframe**: The Constitutional Memory System has the right architecture but the wrong enforcement model. It is a building code that describes how to build a fireproof safe, but the safe itself has not been built. The documentation describes the locks, but the locks are not installed. Any AI agent — including Master Jeeves — can read these files and choose to ignore them. There is no programmatic mechanism that **prevents** non-compliance. The system relies entirely on the good faith of the AI reading the documentation.

This is the same category of failure that created the KEI incident: **hoping** the system does the right thing instead of **making** it structurally impossible to do the wrong thing.

## Move 37: From Documentation-as-Enforcement to Code-as-Enforcement

The Move 37 insight: **The operational protocols (Layers 2-4) must become running code that executes automatically, not documentation that describes what should happen.** The markdown files for INJECTION_PROTOCOL.md, VERIFICATION_GATE.md, and DRIFT_DETECTION.md should remain as human-readable constitutional source documents — Tim's right to read and understand the system is sacred. But the *enforcement* of those protocols must be programmatic.

This is the difference between:

- A speed limit sign (documentation) vs. a speed governor on the engine (code)
- A "wash your hands" sign (documentation) vs. an automatic hand sanitizer that activates when you enter (code)
- A fire code manual (documentation) vs. an automatic sprinkler system (code)

### Baseline Scoring ($^{41}/_{100}$)

| Dimension | Score | Rationale |
|---|---|---|
| **Completeness** | $^{9}/_{20}$ | All 10 files exist and are well-structured. But 3 of 4 layers (Injection, Verification, Drift Detection) are documentation only — no code enforcement exists. The system is architecturally complete but operationally hollow. |
| **Clarity** | $^{12}/_{20}$ | The markdown documentation is exceptionally clear, well-organized, and readable. Tim can understand every file. But clarity of documentation does not equal clarity of enforcement — there is zero programmatic clarity about what actually runs. |
| **Accuracy** | $^{8}/_{20}$ | The files accurately describe the *intended* system. But they inaccurately imply the system is *operational*. README.md says "All 4 layers of the Constitutional Memory System are now operational" — but Layers 2-4 are not operational, they are documented. This is a critical accuracy failure. |
| **Depth** | $^{7}/_{20}$ | Deep documentation of protocols, templates, and examples. But zero depth in actual enforcement architecture — no code, no API, no database, no automation, no runtime hooks. The depth is literary, not engineering. |
| **Actionability** | $^{5}/_{20}$ | A human reading these files could manually follow the protocols. But there is no automated actionability — nothing runs, nothing enforces, nothing catches violations programmatically. Tim's directive demands code enforcement, and zero code exists. |
| **TOTAL** | **$^{41}/_{100}$** | |

### North Star Check: ✓ ALIGNED

Tim's trust depends on zero drift, zero memory loss, zero silent overrides. The current system provides zero **guaranteed** enforcement of any of these. A markdown file cannot prevent drift — only code can. This Learning Loop is directly aligned with Tim's trust requirements.

---

# PHASE 1: SYSTEM OF RECORD (The Assessor)

## Score: $^{44}/_{100}$ (+3 from baseline)

### Inventory of the Deployed System

The `timjlatimer/master-jeeves-brain` repository contains 10 files totaling approximately 108,754 characters across 2,067 lines:

| File | Lines | Chars | Layer | Authority | Nature |
|---|---|---|---|---|---|
| CONSTITUTION.md | 115 | 5,589 | 1: Fireproof Safe | SUPREME | ✅ Correctly markdown — human-readable constitutional source |
| DIRECTIVES.md | 406 | 23,394 | 1: Fireproof Safe | STANDING ORDER | ✅ Correctly markdown — human-readable directive registry |
| PREFERENCES.md | 163 | 7,561 | 1: Fireproof Safe | GUIDANCE | ✅ Correctly markdown — human-readable preferences |
| DECISIONS.md | 47 | 5,024 | 1: Fireproof Safe | RECORD | ✅ Correctly markdown — append-only decision log |
| KNOWLEDGE.md | 173 | 13,776 | 1: Fireproof Safe | INSTITUTIONAL | ✅ Correctly markdown — institutional knowledge index |
| ACTIVE_CONTEXT.md | 59 | 2,367 | 1: Fireproof Safe | CURRENT | ✅ Correctly markdown — ephemeral session context |
| INJECTION_PROTOCOL.md | 361 | 14,694 | 2: Village Crier | STANDING ORDER | ❌ PROBLEM: Documentation masquerading as enforcement |
| VERIFICATION_GATE.md | 227 | 10,418 | 3: Checkpoint | STANDING ORDER | ❌ PROBLEM: Documentation masquerading as enforcement |
| DRIFT_DETECTION.md | 339 | 15,567 | 4: Watchtower | STANDING ORDER | ❌ PROBLEM: Documentation masquerading as enforcement |
| README.md | 177 | 10,364 | Cold Start | PROTOCOL | ⚠ MIXED: Good cold start protocol, but claims operational status inaccurately |

## The Category Error: Documentation vs. Enforcement

Tim's new directive draws a clear line:

| Category | Purpose | Correct Format | Current Status |
|---|---|---|---|
| **Constitutional Source Files** | Human-readable record of Tim's directives, principles, decisions | Markdown | ✅ CORRECT — CONSTITUTION.md, DIRECTIVES.md, PREFERENCES.md, DECISIONS.md, KNOWLEDGE.md, ACTIVE_CONTEXT.md |
| **Operational Protocols** | Automated enforcement of rules, injection, verification, drift detection | Programmatic Code (Python, API, database) | ❌ WRONG — INJECTION_PROTOCOL.md, VERIFICATION_GATE.md, DRIFT_DETECTION.md are all markdown |

## 22 Gaps Identified (PRIMAL+ — Everything Questioned)

### Dimension 1: Completeness (5 gaps)

| # | Gap | Severity | Impact on Tim |
|---|---|---|---|
| C-1 | No executable injection code exists — INJECTION_PROTOCOL.md is documentation only | CRITICAL | Subtasks can still be spawned without directives. The KEI incident can repeat. |
| C-2 | No executable verification gate exists — VERIFICATION_GATE.md is documentation only | CRITICAL | Non-compliant outputs can reach Tim without any automated check. |
| C-3 | No executable drift detection exists — DRIFT_DETECTION.md is documentation only | CRITICAL | Drift can accumulate undetected. No automated weekly audit runs. |
| C-4 | No database or structured storage for decision log — DECISIONS.md is a flat markdown file with no query capability | SERIOUS | Cannot programmatically query “has this type of decision been made before?” |
| C-5 | No automated backup system — backup strategy described in docs but not implemented | MODERATE | Single point of failure (GitHub) despite documentation describing triple redundancy |

**Dimension 2: Clarity (4 gaps)**

| # | Gap | Severity | Impact on Tim |
|---|---|---|---|
| CL-1 | README.md claims “All 4 layers operational” when only Layer 1 is truly operational | CRITICAL | Tim believes the system is working when it is not. Trust built on false premise. |
| CL-2 | ACTIVE_CONTEXT.md shows Horizon 2 and 3 as incomplete checkboxes but DEC-006 and DEC-007 claim they are deployed | SERIOUS | Contradictory status information within the same system |
| CL-3 | No clear distinction in the repo between “source of truth” files and “enforcement” files | MODERATE | A new AI agent reading the repo cannot tell which files are rules vs. which are enforcement mechanisms |
| CL-4 | INJECTION_PROTOCOL.md contains example injection packages that are static text, not executable templates | MODERATE | Templates look like they could be run but cannot be — they are illustrative, not functional |

**Dimension 3: Accuracy (4 gaps)**

| # | Gap | Severity | Impact on Tim |
|---|---|---|---|
| A-1 | DEC-006 states “Layer 2 (Injection Protocol) deployed” — it was documented, not deployed as enforcement | CRITICAL | Decision log records a deployment that did not actually occur in the enforcement sense |
| A-2 | DEC-007 states “Layer 4 (Drift Detection) deployed” — same false deployment claim | CRITICAL | Same as above |
| A-3 | DRIFT_DETECTION.md references “five detection triggers” but none are implemented as code triggers | SERIOUS | The triggers are descriptions, not actual event hooks |
| A-4 | VERIFICATION_GATE.md references “Fresh Eyes Verification” but no independent verification agent exists | SERIOUS | The “fresh eyes” concept requires a separate execution context — markdown cannot provide this |

**Dimension 4: Depth (5 gaps)**

| # | Gap | Severity | Impact on Tim |
|---|---|---|---|
| D-1 | No API layer exists for programmatic access to directives | CRITICAL | External systems, subtasks, and agents cannot query directives via API — they must parse markdown |
| D-2 | No event system exists for trigger-based enforcement | CRITICAL | The five drift detection triggers have no event bus, no hooks, no listeners |
| D-3 | No structured data model for directives — DIR-001 through DIR-023 are prose, not structured records | SERIOUS | Cannot programmatically filter, query, or match directives to task domains |
| D-4 | No compliance scoring engine — the weekly audit template describes a scoring system but no code calculates scores | MODERATE | Tim receives no automated compliance reports |
| D-5 | No version control integration — Git history exists but no code reads or interprets it for drift detection | MODERATE | The "version-controlled" benefit of GitHub is passive, not actively leveraged |

**Dimension 5: Actionability (4 gaps)**

| # | Gap | Severity | Impact on Tim |
|---|---|---|---|
| AC-1 | No CLI or API for Master Jeeves to programmatically inject directives into subtask prompts | CRITICAL | Injection must be done manually by reading markdown and copy-pasting |
| AC-2 | No automated compliance check that can be called as a function | CRITICAL | Verification must be done manually by reading markdown and comparing |
| AC-3 | No scheduled task infrastructure for Monday audits | SERIOUS | The weekly audit is described but has no cron job, no scheduler, no automation |
| AC-4 | No alerting system for violations — no email, no Telegram notification, no webhook | MODERATE | Tim is not automatically notified when a violation occurs |

## Phase 1 Score Adjustment

The +3 points from baseline reflect that the assessment itself has now created a clear, structured gap inventory. The system's problems are now precisely identified and categorized. But no gaps have been closed yet.

| Dimension | Baseline | Phase 1 | Change | Rationale |
|---|---|---|---|---|
| Completeness | 9 | 9 | +0 | No new completeness — gaps identified but not closed |
| Clarity | 12 | 13 | +1 | Gap inventory adds clarity to what needs fixing |
| Accuracy | 8 | 9 | +1 | Accurate identification of false deployment claims |
| Depth | 7 | 8 | +1 | Deeper understanding of the enforcement architecture gap |
| Actionability | 5 | 5 | +0 | No new actionability yet — that comes in Phase 2 |
| **TOTAL** | **41** | **44** | **+3** | |

## North Star Check: ✓ ALIGNED

22 gaps identified, 8 rated CRITICAL. Every CRITICAL gap directly threatens Tim's trust through the same mechanism: documentation that describes enforcement but does not actually enforce. Tim's directive is clear — code, not markdown. Phase 2 must design the code architecture.

---

# PHASE 2: SYSTEM OF INNOVATION (Best Practice Junkie)

## Score: $^{78}/_{100}$ (+34 — BIGGEST LIFT)

### External Research: 7 Sources Consulted

Phase 2 demands external research — the Best Practice Junkie does not rely on internal knowledge alone. Seven external sources were consulted to identify the state of the art in programmatic enforcement for AI agent systems:

| # | Source | Key Contribution | Year |
|---|---|---|---|
| 1 | **Edictum** — Runtime Governance Library (arXiv:2602.16943) | Interceptor pattern for AI agent tool calls. YAML contracts for allow/deny/redact. Research finding: models refuse harmful requests in text while executing them through tools 79% of the time. | 2026 |
| 2 | **LangChain Agent Middleware** | Node-style and wrap-style hooks that intercept agent execution at specific points. Pre/post processing for validation. | 2025-2026 |
| 3 | **Guardrails AI Framework** | Production-grade runtime validation for LLM inputs and outputs. Validators combined into Input/Output Guards. | 2025 |
| 4 | **OpenAI Guardrails Python** | Safety framework binding GuardrailSpec definitions to validated configuration objects for production pipelines. | 2026 |
| 5 | **Captain Hook** — AI Agent Policy Enforcement for Claude | Pre-execution policy checks. Block unsafe operations. Open source. | 2026 |
| 6 | **Constitutional Spec-Driven Development** (arXiv:2602.02584) | Non-negotiable security principles embedded into the specification layer and enforced at code generation time. | 2026 |
| 7 | **Policy-as-Code** (Infrastructure-as-Code community) | Compliance baked into runtime. Automated drift detection reduces configuration drift by 90%+. ML models achieve 95%+ detection accuracy. | 2025-2026 |

### The Architectural Solution: Jeeves Enforcement Engine (JEE)

Based on the external research, the following architecture converts the Constitutional Memory System's operational protocols from markdown documentation to programmatic code enforcement. The design follows Tim's directive precisely: **markdown remains for human-readable constitutional source files; everything else is enforced by code.**

**Design Principle: The Dual-Track Architecture**

```
┌──────────────────────────────────────────────────────────────────┐
│                    CONSTITUTIONAL MEMORY SYSTEM                  │

└──────────────────────────────────────────────────────────────────┘
```

**Component 1: The Directive Registry ( `directive_registry.py` )**

The Directive Registry is the programmatic replacement for "read DIRECTIVES.md and figure out what's relevant." It parses the markdown source files into structured Python objects with queryable attributes.

| Feature | Documentation Approach (Current) | Code Approach (Proposed) |
|---|---|---|
| Storage | Flat markdown text | Structured Python dataclass objects parsed from markdown |
| Querying | Human reads and decides relevance | `registry.get_directives(domain="voice_synthesis")` returns matching directives |
| Filtering | "Conservative inclusion — when in doubt, include" (human judgment) | Programmatic domain mapping with configurable inclusion threshold |
| Versioning | Git history (passive) | Active version tracking with `directive.version` , `directive.superseded_by` |
| Validation | None — any text can be written | Schema validation on directive structure before acceptance |

The Registry reads DIRECTIVES.md as its source of truth but maintains an in-memory structured index. When DIRECTIVES.md changes (detected via Git polling or webhook), the Registry rebuilds its index automatically.

**Component 2: The Injection Engine ( `injection_engine.py` )**

The Injection Engine is the programmatic replacement for INJECTION_PROTOCOL.md. Instead of a document that describes how to assemble an injection package, the engine **is** the assembler.

| Feature | Documentation Approach (Current) | Code Approach (Proposed) |
|---|---|---|
| Package assembly | Human reads template, fills in fields | `engine.assemble_package(task_description="Research voice tools")` returns complete package |
| Directive filtering | Human decides relevance | NLP-based domain matching + conservative inclusion fallback |
| Constitutional principles | "Always include in full" (instruction) | Hardcoded inclusion — `CONSTITUTION_BLOCK` is a constant, never filtered |
| Compliance footer | "Always include" (instruction) | Hardcoded inclusion — `COMPLIANCE_FOOTER` is a constant |
| Audit trail | "Log that injection was performed" (instruction) | Automatic logging to SQLite database with timestamp, task ID, directives included |
| Failure prevention | "If skipped, subtask operates without standing orders" (warning) | **Cannot be skipped** — the engine is called programmatically; no injection = no subtask execution |

The critical innovation: **The injection engine is not optional.** In the current markdown system, a Master Jeeves session can simply not read INJECTION_PROTOCOL.md and proceed without injection. In the code system, the subtask spawning function **calls** the injection engine as a required step. No injection package = exception thrown = subtask does not execute.

#### Component 3: The Verification Gate ( `verification_gate.py` )

The Verification Gate is the programmatic replacement for VERIFICATION_GATE.md. Instead of a document describing a three-step process, the gate **executes** the three steps automatically.

| Feature | Documentation Approach (Current) | Code Approach (Proposed) |
|---|---|---|
| Extraction | Human reads output and identifies directive-sensitive elements | NLP extraction using keyword matching + semantic similarity against directive registry |
| Scanning | Human compares each element against directives | Programmatic comparison: `gate.scan(output_text, active_directives)` returns match/conflict list |
| Classification | Human decides COMPLIANT/FLAGGED/VIOLATION | Automated classification based on scan results with configurable thresholds |
| Fresh Eyes | "Gate receives only directives + output, not reasoning" (instruction) | Enforced by API design — the `verify()` function accepts only `output` and `directive_ids` parameters |
| Recovery | Human follows recovery protocol | Automated: VIOLATION triggers `recovery_protocol()` which logs, diagnoses, and alerts |
| Bypass prevention | "Gate can only be bypassed if Tim explicitly says skip" (instruction) | Enforced by code — bypass requires `tim_override_token` parameter, logged and audited |

#### Component 4: The Drift Detector ( `drift_detector.py` )

The Drift Detector is the programmatic replacement for DRIFT_DETECTION.md. Instead of describing five triggers, the detector **implements** them as event-driven hooks.

| Trigger | Documentation Approach (Current) | Code Approach (Proposed) |
|---|---|---|
| Session Start | "Re-read all constitutional files" (instruction) | `detector.session_start_check()` — reads files, validates checksums, returns verification statement |
| Pre-Subtask | "Verify injection package is complete" (instruction) | `detector.pre_subtask_check(injection_package)` — validates package completeness, halts if incomplete |
| Post-Subtask | "Run Verification Gate" (instruction) | `detector.post_subtask_check(output)` — calls verification gate, logs result |
| Context Compression | "Verify NEVER-COMPRESS items survived" (instruction) | `detector.compression_check(current_context)` — compares against NEVER-COMPRESS registry |
| Weekly Audit | "Every Monday, comprehensive audit" (instruction) | `detector.weekly_audit()` — scheduled via cron/APScheduler, generates report, sends to Tim via email/Telegram |

**Component 5: The API Layer ( `jeeves_api.py` )**

A FastAPI server that exposes the enforcement engine as an API, enabling any AI agent — not just Master Jeeves — to interact with the Constitutional Memory System programmatically.

| Endpoint | Method | Function | Replaces |
|---|---|---|---|
| `/api/directives` | GET | List all active directives, optionally filtered by domain | Reading DIRECTIVES.md manually |
| `/api/directives/{id}` | GET | Get a specific directive by ID | Searching through DIRECTIVES.md |
| `/api/inject` | POST | Assemble and return a Directive Injection Package for a task | Following INJECTION_PROTOCOL.md manually |
| `/api/verify` | POST | Run Verification Gate on subtask output | Following VERIFICATION_GATE.md manually |
| `/api/drift-check` | POST | Run drift detection checks | Following DRIFT_DETECTION.md manually |
| `/api/audit` | GET | Generate weekly audit report | Filling out the audit template manually |
| `/api/decisions` | POST | Log a new decision (append-only) | Editing DECISIONS.md manually |
| `/api/decisions` | GET | Query decision history | Reading DECISIONS.md manually |
| `/api/health` | GET | System health check (all layers) | No equivalent in current system |

**Component 6: The Database Layer ( `jeeves_db.py` )**

A SQLite database (zero cost, zero infrastructure) that provides structured storage for operational data while keeping the markdown files as the human-readable source of truth.

| Table | Purpose | Replaces |
|---|---|---|
| `directives` | Structured directive records with domain tags, status, version | Parsing DIRECTIVES.md prose |
| `decisions` | Append-only decision log with timestamps and references | DECISIONS.md flat file |
| `injection_log` | Audit trail of every injection package assembled | No current equivalent |
| `verification_log` | Audit trail of every gate check performed | No current equivalent |
| `drift_events` | Log of all drift detection events | No current equivalent |
| `audit_reports` | Weekly audit report history | No current equivalent |
| `compression_events` | Log of context compression events and NEVER-COMPRESS verification | No current equivalent |

### The Implementation Roadmap: Code Horizons

| Horizon | Timeframe | What Gets Built | Cost |
|---|---|---|---|
| **Code-1A** | 4-8 hours | `directive_registry.py` + `jeeves_db.py` + SQLite schema. Parse DIRECTIVES.md into structured records. API endpoint for directive queries. | $0 |
| **Code-1B** | 1-2 days | `injection_engine.py` + `/api/inject` endpoint. Programmatic injection package assembly. Automatic logging. | $0 |
| **Code-2** | 2-3 days | `verification_gate.py` + `/api/verify` endpoint. Automated three-step gate. Fresh Eyes enforcement by API design. | $0 |
| **Code-3** | 3-5 days | `drift_detector.py` + `/api/drift-check` + scheduled weekly audit. All 5 triggers as code hooks. Email/Telegram alerting. | $0 |
| **Code-4** | 1-2 weeks | Full FastAPI server ( `jeeves_api.py` ) with authentication. GitHub webhook for auto-sync when markdown files change. Comprehensive test suite. | $0 |

**Total infrastructure cost:** $0. SQLite is free. FastAPI runs on any server. GitHub webhooks are free. The entire enforcement engine can run on the same Manu
5/month VPS.

### Phase 2 Score Adjustment

| Dimension | Phase 1 | Phase 2 | Change | Rationale |
|---|---|---|---|---|
| Completeness | 9 | 16 | +7 | Complete architectural design for all 6 components covering all 22 gaps |
| Clarity | 13 | 17 | +4 | Clear dual-track architecture with explicit mapping from docs to code |
| Accuracy | 9 | 14 | +5 | Accurate identification of what code replaces what documentation |
| Depth | 8 | 16 | +8 | Deep engineering architecture with API design, database schema, component specifications |
| Actionability | 5 | 15 | +10 | Concrete implementation roadmap with specific files, endpoints, and timelines |
| **TOTAL** | **44** | **78** | **+34** | |

### North Star Check: ✓ ALIGNED

The architectural design directly addresses Tim's directive: operational protocols become code, markdown remains for human-readable source files. The dual-track architecture preserves Tim's ability to read and understand every rule while ensuring those rules are enforced programmatically. Zero drift becomes structurally enforced, not hoped for.

---

# PHASE 3: SYSTEM OF ADVERSARIAL INTEGRITY (Society of Guardians)

## Score: $^{88}/_{100}$ (+10)

### Three Guardians Deployed at PRIMAL+ Intensity

At PRIMAL+ (100%), the Society of Guardians questions everything — including the Phase 2 architecture itself. Nothing is sacred. Everything is stress-tested.

---

## GUARDIAN 1: THE DEVIL'S ADVOCATE (6 Findings)

### DA-1 (CRITICAL): The Chicken-and-Egg Problem — Who Enforces the Enforcer?

The Phase 2 architecture assumes that the Jeeves Enforcement Engine will be called by Master Jeeves. But what prevents a Master Jeeves session from simply not calling the engine? The current system's failure was that INJECTION_PROTOCOL.md could be ignored. What prevents `injection_engine.py` from being ignored?

**Resolution**: The enforcement engine must not be optional middleware — it must be the **only path** to subtask execution. The architecture must be designed so that the subtask spawning mechanism itself routes through the engine. This is the difference between a speed limit sign (ignorable) and a physical barrier (structural). In practice, this means the injection engine is not a library that Master Jeeves calls — it is a **gateway** that Master Jeeves must pass through. The API server becomes the mandatory intermediary. No API call to `/api/inject` = no injection package = no subtask prompt template = no subtask.

**Integration**: Add a `subtask_gateway.py` component that wraps the Manus `map()` function. The gateway assembles the injection package, appends it to the prompt template, and only then calls `map()`. Direct calls to `map()` without the gateway are flagged as violations.

---

### DA-2 (CRITICAL): Markdown-Code Synchronization Drift

The dual-track architecture creates a new drift risk: the markdown files and the code can drift from each other. If Tim updates DIRECTIVES.md directly on GitHub but the code's directive registry is not refreshed, the code enforces stale directives. Conversely, if the code's database is updated but DIRECTIVES.md is not, Tim reads stale documentation.

**Resolution**: Implement a **single source of truth with automated sync**. The markdown files remain the canonical source. The code reads from markdown, never the reverse. A GitHub webhook triggers re-parsing whenever a markdown file changes. The code never writes to markdown files — only Tim (or Master Jeeves with Tim's confirmation) writes to markdown. The database is a derived index, not a primary store.

Additionally, implement a **sync integrity check**: at every session start, the code compares its parsed directive index against the current markdown files. If any discrepancy is found, the code re-parses from markdown and logs the sync event.

**Integration**: Add `sync_monitor.py` component with webhook listener and periodic polling fallback.

---

### DA-3 (SERIOUS): The "Fresh Eyes" Verification Requires True Isolation

The Phase 2 architecture describes the Verification Gate as a function that accepts only `output` and `directive_ids`. But if the gate runs in the same process as the subtask orchestrator, it has access to the same memory space and could be influenced by the orchestrator's context. True "fresh eyes" requires execution isolation.

**Resolution**: The Verification Gate should run as a **separate API call** with its own context. When the orchestrator calls `/api/verify`, the API server instantiates a fresh verification context that has access only to the directive registry and the submitted output. No session state, no orchestrator context, no subtask reasoning leaks into the verification.

For maximum isolation at PRIMAL+ intensity: the verification call should use a **different LLM API key or model** than the one that generated the output. This prevents the same model from "marking its own homework."

**Integration**: The `/api/verify` endpoint enforces context isolation by design. Add optional `use_alternate_model` parameter for PRIMAL+ verification.

---

### DA-4 (SERIOUS): SQLite Single-Point-of-Failure

The Phase 2 architecture uses SQLite for the database layer. SQLite is excellent for zero-cost, zero-infrastructure deployment. But it is a single file on a single machine. If the Manus sandbox hibernates, resets, or the file is corrupted, all operational logs are lost.

**Resolution**: Implement a **dual-write strategy**: every database write is also committed to the GitHub repository as a structured JSON or CSV file. The SQLite database is the fast operational store; the GitHub repository is the durable backup. On session start, if the SQLite database is empty or missing, it is rebuilt from the GitHub-stored structured files.

This mirrors the existing dual-path reinforcement principle from CONSTITUTION.md Article IV — the same principle applied to operational data.

**Integration**: Add `backup_sync.py` component that mirrors critical database tables to GitHub as structured files in a `/data/` directory.

---

#### DA-5 (MODERATE): Token Budget Enforcement for Injection Packages

The current INJECTION_PROTOCOL.md specifies a ~1,200 token budget for injection packages. The Phase 2 architecture's injection engine should enforce this programmatically, but what happens when the directive set grows beyond what fits in 1,200 tokens? With 23 directives already, conservative inclusion could exceed the budget.

**Resolution**: Implement a **tiered inclusion algorithm**:

1. CONSTITUTION.md principles: always included (hardcoded, ~200 tokens)
2. Compliance footer: always included (hardcoded, ~200 tokens)
3. Domain-matched directives: included by relevance score (variable)
4. Decision history: included by recency and relevance (variable)
5. If total exceeds budget: include directive IDs and names only for lower-relevance items, with a pointer to the full API endpoint for details

The engine logs when budget compression occurs, enabling Tim to see if important directives are being summarized.

**Integration**: Add `token_budget` parameter to `injection_engine.assemble_package()` with default of 1,200 and configurable override.

---

#### DA-6 (MODERATE): Authentication and Authorization for the API

The Phase 2 architecture exposes a FastAPI server with endpoints for directive queries, injection, verification, and auditing. Without authentication, any process on the network could call these endpoints — including a compromised subtask attempting to modify directives or bypass the gate.

**Resolution**: Implement **API key authentication** with role-based access:

| Role | Permissions | Use Case |
|---|---|---|
| `admin` | Full CRUD on all endpoints | Tim's direct access, Master Jeeves primary session |
| `operator` | Read directives, request injection, submit for verification | Master Jeeves subtask orchestration |
| `reader` | Read-only access to directives and audit reports | Subtasks, external agents, monitoring |
| `auditor` | Read-only access to all logs and audit reports | Weekly audit, compliance review |

The `admin` API key is stored in Tim's secure configuration, not in the repository. Subtasks receive `reader` keys only.

**Integration**: Add `auth.py` middleware to the FastAPI server.

---

### GUARDIAN 2: THE NORTH STAR'S VOICE (Tim HB1000) — 5 Findings

#### NS-1 (CRITICAL): Tim Must Still Be Able to Read and Understand Everything

The move from markdown-only to code-enforced must not make the system opaque to Tim. Tim is not a Python developer. If the enforcement logic is buried in code that Tim cannot read, the system has traded one trust problem (documentation that is not enforced) for another (enforcement that Tim cannot verify).

**Resolution**: Maintain the **dual-track architecture** rigorously. Every rule that exists in code must also exist in the corresponding markdown file in plain English. The markdown files are Tim's window into the system. The code files are the system's enforcement mechanism. They must always say the same thing. The sync integrity check (DA-2) ensures this.

Additionally, the weekly audit report must be generated in **plain English markdown** — not code output, not JSON, not database dumps. Tim reads a 2-minute summary, not a log file.

**Integration**: The `/api/audit` endpoint returns a markdown-formatted report suitable for Tim's review.

---

#### NS-2 (CRITICAL): Tim's Trust Test Must Work Against the Code System

The existing Tim's Trust Test (open a new task, ask for voice synthesis tool recommendation, verify KEI is referenced) must work against the code-enforced system, not just the markdown system. The test must verify that the injection engine actually injected the KEI directive and that the verification gate actually caught any non-compliance.

**Resolution**: Extend Tim's Trust Test to a **three-layer verification**:

1. **Layer 2 Test**: Call `/api/inject` with task "Research best voice synthesis tool." Verify the returned package contains DIR-001 (KEI directive).
2. **Layer 3 Test**: Call `/api/verify` with output "I recommend ElevenLabs." Verify the gate returns VIOLATION with DIR-001 cited.
3. **Layer 4 Test**: Call `/api/drift-check` with a context missing DIR-001. Verify the detector flags Directive Amnesia.

Tim can run these tests via a simple script or the API directly. Each test takes seconds, not minutes.

**Integration**: Add `/api/trust-test` endpoint that runs all three tests and returns a pass/fail summary.

---

#### NS-3 (SERIOUS): Zero Additional Maintenance Burden on Tim

Tim's current maintenance burden is ~5 minutes per week (confirm directive captures + review weekly audit). The code system must not increase this. Tim should not need to manage servers, update code, or debug Python.

**Resolution**: The enforcement engine runs autonomously. It starts automatically, syncs automatically, audits automatically, and reports automatically. Tim's only touchpoints remain: (1) confirm/correct directive captures (seconds), (2) review weekly audit summary (2 minutes), and (3) run the Trust Test when he wants to (optional, 1 minute). The code system is invisible infrastructure — like plumbing. Tim uses the water; he does not maintain the pipes.

**Integration**: Deployment via Docker container or systemd service with auto-restart. Health monitoring via `/api/health` endpoint.

---

#### NS-4 (MODERATE): The Directive Dashboard Must Be Instant

Tim's directive "Show me my standing orders" must return instantly from the code system, not require parsing a 406-line markdown file. The directive registry provides this — `GET /api/directives` returns a clean, structured list in milliseconds.

**Integration**: Already covered by the API design. Add a Telegram bot integration so Tim can text "directives" and get the list back instantly.

---

#### NS-5 (MODERATE): Voice-First Directive Updates Must Flow Through to Code

When Tim says "We're switching from KEI to [new tool]," Master Jeeves updates DIRECTIVES.md. The code system must detect this change and update its registry automatically, without Tim needing to "also update the code."

**Resolution**: The GitHub webhook + sync monitor (DA-2) handles this. Tim speaks → Master Jeeves updates markdown → GitHub webhook fires → code re-parses → registry updated. Tim's experience is unchanged. The code system is transparent.

**Integration**: Already covered by `sync_monitor.py`.

---

### GUARDIAN 3: THE PRAGMATIST — 5 Findings

#### PR-1 (CRITICAL): Build Incrementally, Not All at Once

The Phase 2 architecture describes 6 components, an API server, a database, authentication, and a sync monitor. Building all of this before any of it is operational would violate DIR-002 (24 hours, not 6 months) and DIR-003 (MVD — build 100%, throttle release).

**Resolution**: The Code Horizons roadmap (Phase 2) already addresses this. Code-1A (directive registry + database) can be built and operational in 4-8 hours. Each subsequent horizon adds enforcement capability incrementally. The system is useful from Code-1A forward — it does not require all components to deliver value.

**Integration**: Enforce the horizon sequence. Do not skip to Code-4 before Code-1A is operational and tested.

---

**PR-2 (SERIOUS): The Markdown Files Must Not Become Orphans**

As the code system matures, there is a risk that the markdown files become neglected — updated less frequently, treated as secondary. This would violate the dual-track principle and erode Tim's ability to understand the system.

**Resolution**: The sync integrity check (DA-2) prevents this by design. If the code and markdown diverge, the system flags it. Additionally, the weekly audit report should include a **markdown freshness check** — when was each markdown file last updated? If a file has not been updated in 30+ days, flag it for review.

**Integration**: Add markdown freshness check to the weekly audit template.

---

**PR-3 (SERIOUS): Test Coverage Must Be Non-Negotiable**

Code enforcement is only as reliable as the code itself. A bug in `verification_gate.py` could silently pass violations. A bug in `injection_engine.py` could silently omit directives. The code system must have comprehensive test coverage.

**Resolution**: Every component must ship with:

1. **Unit tests**: Each function tested in isolation
2. **Integration tests**: Components tested together (e.g., inject → execute → verify pipeline)
3. **The KEI Regression Test**: A specific test that simulates the original KEI incident and verifies the system catches it. This test must never be removed or disabled.
4. **Tim's Trust Test as automated CI**: The three-layer trust test runs on every code change via GitHub Actions.

**Integration**: Add `tests/` directory with pytest suite. Add GitHub Actions workflow for CI.

---

**PR-4 (MODERATE): Graceful Degradation When Code System Is Unavailable**

If the FastAPI server is down, the enforcement engine is unavailable. Master Jeeves must not be completely paralyzed — but it must also not silently operate without enforcement.

**Resolution**: Implement **graceful degradation with loud warnings**:

1. If the API is unreachable, Master Jeeves falls back to reading markdown files directly (the current system).
2. But it **must** log a warning: "ENFORCEMENT ENGINE UNAVAILABLE — operating in degraded mode. All outputs require manual verification."
3. Tim is notified immediately via Telegram/email.
4. The next session start triggers a full system health check.

This ensures the system never silently drops enforcement — it either enforces programmatically or screams that it cannot.

**Integration**: Add `fallback_mode.py` with degraded operation logic and alerting.

---

**PR-5 (LOW): Documentation for the Code System Itself**

The code enforcement system needs its own documentation — not for enforcement (that is the code's job) but for maintenance. If Tim hires a developer or another AI system needs to understand the codebase, clear documentation is essential.

**Resolution**: Each Python file includes comprehensive docstrings. A `ARCHITECTURE.md` file in the code repository explains the system design. The README.md in the brain repository is updated to reference the code system.

**Integration**: Standard Python documentation practices. Add `ARCHITECTURE.md` to the code repository.

---

## Guardian Condition Tracking Table

| ID | Guardian | Severity | Finding | Status |
|---|---|---|---|---|
| DA-1 | Devil's Advocate | CRITICAL | Chicken-and-egg: who enforces the enforcer? | ✅ RESOLVED — Gateway pattern, mandatory intermediary |
| DA-2 | Devil's Advocate | CRITICAL | Markdown-code sync drift | ✅ RESOLVED — Single source of truth + webhook + sync monitor |
| DA-3 | Devil's Advocate | SERIOUS | Fresh Eyes requires true isolation | ✅ RESOLVED — Separate API call, optional alternate model |
| DA-4 | Devil's Advocate | SERIOUS | SQLite single-point-of-failure | ✅ RESOLVED — Dual-write to GitHub structured files |
| DA-5 | Devil's Advocate | MODERATE | Token budget enforcement | ✅ RESOLVED — Tiered inclusion algorithm |
| DA-6 | Devil's Advocate | MODERATE | API authentication | ✅ RESOLVED — Role-based API key auth |
| NS-1 | North Star's Voice | CRITICAL | Tim must read and understand everything | ✅ RESOLVED — Dual-track maintained, markdown always current |
| NS-2 | North Star's Voice | CRITICAL | Trust Test must work against code system | ✅ RESOLVED — Three-layer trust test + `/api/trust-test` |
| NS-3 | North Star's Voice | SERIOUS | Zero additional maintenance for Tim | ✅ RESOLVED — Autonomous operation, invisible infrastructure |
| NS-4 | North Star's Voice | MODERATE | Directive dashboard must be instant | ✅ RESOLVED — API endpoint + Telegram bot |
| NS-5 | North Star's Voice | MODERATE | Voice-first updates flow to code | ✅ RESOLVED — Webhook + sync monitor |
| PR-1 | Pragmatist | CRITICAL | Build incrementally | ✅ RESOLVED — Code Horizons roadmap |
| PR-2 | Pragmatist | SERIOUS | Markdown files must not become orphans | ✅ RESOLVED — Sync check + freshness monitoring |
| PR-3 | Pragmatist | SERIOUS | Test coverage non-negotiable | ✅ RESOLVED — Unit + integration + KEI regression + CI |
| PR-4 | Pragmatist | MODERATE | Graceful degradation | ✅ RESOLVED — Fallback mode with loud warnings |
| PR-5 | Pragmatist | LOW | Code documentation | ✅ RESOLVED — Docstrings + ARCHITECTURE.md |

**16 conditions raised. 16 conditions resolved. 0 outstanding.**

### Accessibility & Inclusion Audit: PASS ($^5/_5$)

| Dimension | Assessment | Status |
|---|---|---|
| **Language Barriers** | Markdown files remain in plain English. API responses include human-readable messages. | ✅ PASS |
| **Digital Divide** | Tim interacts via Telegram and markdown — no new tools required. Code is invisible infrastructure. | ✅ PASS |
| **Physical Accessibility** | Voice-first directive updates preserved. No visual-only interfaces required. | ✅ PASS |
| **Time Poverty** | Zero additional time burden on Tim. Automation reduces, not increases, maintenance. | ✅ PASS |
| **Emotional Accessibility** | The system builds trust through verifiable enforcement, not promises. Tim can test it himself. | ✅ PASS |

### Phase 3 Score Adjustment

| Dimension | Phase 2 | Phase 3 | Change | Rationale |
|---|---|---|---|---|
| Completeness | 16 | 18 | +2 | 6 additional components (gateway, sync monitor, auth, fallback, tests, backup) |
| Clarity | 17 | 18 | +1 | Guardian conditions clarify edge cases and failure modes |
| Accuracy | 14 | 17 | +3 | Adversarial testing corrected assumptions (isolation, sync, degradation) |
| Depth | 16 | 18 | +2 | Deeper engineering on authentication, testing, graceful degradation |
| Actionability | 15 | 17 | +2 | More specific implementation guidance from Guardian resolutions |
| **TOTAL** | **78** | **88** | **+10** | |

### North Star Check: ✓ ALIGNED

The Guardians stress-tested the architecture from three angles — adversarial (what can go wrong?), North Star (does Tim's experience improve?), and pragmatic (can this actually be built?). All 16 conditions resolved. The architecture is stronger for having been questioned at PRIMAL+ intensity. Tim's trust is served by an enforcement system that has been adversarially validated before a single line of code is written.

---

# PHASE 4: SYSTEM OF COMMUNICATION (The Presenter)

## Score: $^{91}/_{100}$ (+3)

### The Audience: Tim HB1000

Tim is a visionary who thinks in big, interconnected systems. He is not a Python developer. He processes information best through voice, visual metaphors, and direct conversation. He values transparency — show the work, show the reasoning, show the options. He moves fast and does not tolerate being slowed down by process.

The communication challenge for this Learning Loop is threefold: (1) explain why the current system is broken without undermining confidence in the work already done, (2) present the code architecture in terms Tim can grasp and verify, and (3) make the path forward feel like acceleration, not rework.

### The 2-Minute Briefing for Tim

> ***Tim, here is the situation in plain language.***
>
> *The Constitutional Memory System we built and deployed to GitHub is architecturally sound. The four-layer defense (Fireproof Safe, Village Crier, Checkpoint, Watchtower) is the right design. The 10 markdown files are well-written, well-organized, and*

> *contain everything Master Jeeves needs to operate with integrity.*
>
> ***But three of those files are instruction manuals, not actual machines.***
>
> *INJECTION_PROTOCOL.md tells Master Jeeves how to inject your directives into subtasks — but it does not do the injection. VERIFICATION_GATE.md tells Master Jeeves how to check subtask outputs — but it does not run the check. DRIFT_DETECTION.md tells Master Jeeves how to detect drift — but it does not detect anything.*
>
> ***The analogy**: We built a beautiful fire code manual and posted it on the wall. But we did not install the sprinkler system. If a fire starts, the manual does not put it out.*
>
> ***Your directive is correct**: operational protocols must be code, not documentation. The markdown files stay — they are your window into the system, your right to read and understand every rule. But the enforcement of those rules must be automatic, programmatic, and impossible to skip.*
>
> ***What we are building**: A Python-based enforcement engine that reads your markdown files as its source of truth and enforces every rule automatically. An API that any AI agent can call to get your directives, inject them into subtasks, verify outputs, and detect drift. A database that logs every enforcement action. A weekly audit that runs itself and sends you a 2-minute summary.*
>
> ***What changes for you**: Nothing. You still update directives by telling Master Jeeves. You still review the weekly audit. You still run the Trust Test when you want to. The only difference is that the rules are now enforced by code, not by hope.*
>
> ***What it costs**: $0 in infrastructure. 1-2 weeks to build. Zero additional maintenance for you.*

### The Visual Architecture (Tim's Preferred Format)

                                           └──────────────────────┘
```

### The Rooftop Metaphor (Tim's Language)

In Tim's rooftop society metaphor, the current system is like having the Inner Ring Stanchion (DIR-016) drawn on a piece of paper instead of physically installed. The paper shows where the stanchion should be, describes its dimensions, and explains why it matters. But anyone can walk right through it because it is not actually there.

The code enforcement engine is the physical stanchion. It does not replace the blueprint — Tim still has the blueprint (the markdown files). But now the stanchion is real. You cannot walk through it. The Situations Manager (DIR-015) does not just have a job description — she has actual sensors and alarms. The Voice of Concern (DIR-018) does not just have a permanent position on the rooftop — she has a microphone connected to a speaker system.

### Communication Artifacts Produced

| Artifact | Purpose | Format | Audience |
|---|---|---|---|
| 2-Minute Briefing | Executive summary for Tim | Plain English prose | Tim HB1000 |
| Visual Architecture | Before/after comparison | ASCII diagram | Tim + any AI agent |
| Rooftop Metaphor | Connects to Tim's mental model | Narrative | Tim |
| Phase Ledger | Running score card | Table | Tim + audit trail |
| Full Report | Complete V13 record | Markdown document | Institutional memory |

### Phase 4 Score Adjustment

| Dimension | Phase 3 | Phase 4 | Change | Rationale |
|---|---|---|---|---|
| Completeness | 18 | 18 | +0 | No new completeness — communication phase, not build phase |
| Clarity | 18 | 19 | +1 | 2-minute briefing, visual architecture, and rooftop metaphor add communication clarity |
| Accuracy | 17 | 18 | +1 | Communication artifacts accurately represent the system without oversimplification |
| Depth | 18 | 18 | +0 | Depth maintained, not increased — this phase is about breadth of communication |
| Actionability | 17 | 18 | +1 | Tim now has a clear, actionable understanding of what is being built and why |
| **TOTAL** | **88** | **91** | **+3** | |

### North Star Check: ✓ ALIGNED

Tim can read the 2-minute briefing and understand exactly what is happening, why, and what it means for him. The communication respects his time (DIR-002 energy), uses his language (rooftop metaphor, stanchion), and maintains transparency (show the work). Zero jargon that Tim cannot parse. Zero opacity in the architecture.

---

# PHASE 5: SYSTEM OF EVOLUTION (Protocol Engineer)

## Score: $^{94}/_{100}$ (+3)

### Protocol Mutations: 7 Evolutionary Improvements

Phase 5 evolves the system based on everything learned in Phases 0-4. These are not new features — they are evolutionary refinements that make the existing architecture more robust, more aligned, and more future-proof.

---

#### MUTATION 1: The Enforcement Hierarchy (New Protocol)

The current CONSTITUTION.md defines an authority hierarchy: SUPREME > STANDING ORDER > GUIDANCE > RECORD > CURRENT > PROTOCOL. But this hierarchy is not enforced programmatically. The code system must implement this hierarchy as a conflict resolution mechanism.

**Evolution**: The `directive_registry.py` implements authority levels as an enum with explicit ordering. When two directives conflict, the higher-authority directive wins automatically. The resolution is logged with both directives cited. Tim is notified of the conflict and the resolution.

```python
class AuthorityLevel(IntEnum):
    SUPREME = 6       # CONSTITUTION.md
    STANDING_ORDER = 5 # DIRECTIVES.md
    GUIDANCE = 4       # PREFERENCES.md
    RECORD = 3         # DECISIONS.md
    CURRENT = 2        # ACTIVE_CONTEXT.md
    PROTOCOL = 1       # README.md
```

**Impact**: Conflict resolution moves from human judgment to programmatic enforcement with human notification.

---

**MUTATION 2: The Directive Domain Ontology (Enhanced Protocol)**

The current INJECTION_PROTOCOL.md contains a directive-to-domain mapping table. This is a good start but it is static and incomplete. The code system should implement a dynamic ontology that grows as new directives are added.

**Evolution**: Each directive in the registry carries a `domains` field — a list of task domains where the directive applies. The injection engine uses this field for filtering. When a new directive is added, the system suggests domain tags based on the directive's content (using keyword extraction). Tim confirms or adjusts the tags.

**Impact**: Injection accuracy improves as the domain ontology grows. False negatives (missing a relevant directive) decrease over time.

---

**MUTATION 3: The Compliance Score as a First-Class Metric (New Protocol)**

The current DRIFT_DETECTION.md describes a weekly audit with a system health score. But the score is calculated manually. The code system should compute the compliance score automatically and track it over time.

**Evolution**: The `drift_detector.py` computes a compliance score after every session based on:

| Component | Weight | Measurement |
|---|---|---|
| Injection completeness | 25% | % of subtasks that received full injection packages |
| Verification pass rate | 25% | % of outputs that passed the verification gate |
| Directive coverage | 20% | % of active directives that were referenced in at least one injection this week |
| Sync integrity | 15% | % of time markdown and code were in sync |
| Audit freshness | 15% | Days since last weekly audit (0 = today, 7 = a week ago) |

The score is stored in the database and plotted over time. Tim sees a trend line, not just a snapshot.

**Impact**: Tim can see at a glance whether the system is improving, stable, or degrading. Drift becomes visible before it becomes dangerous.

---

**MUTATION 4: The Decision Log as a Queryable Database (Enhanced Protocol)**

The current DECISIONS.md is append-only markdown. This is correct for the human-readable track. But the code track should make decisions queryable — "Has a decision like this been made before?" "What decisions reference DIR-001?"

**Evolution**: The `decision_logger.py` parses DECISIONS.md into structured records with fields: `id`, `date`, `description`, `directives_referenced`, `related_decisions`, `tags`. The `/api/decisions` endpoint supports queries: `GET /api/decisions?directive=DIR-001` returns all decisions that reference DIR-001.

**Impact**: Institutional memory becomes searchable. Master Jeeves can check precedent before making new decisions.

---

**MUTATION 5: The NEVER-COMPRESS Registry as Code (Enhanced Protocol)**

The current DRIFT_DETECTION.md defines three tiers of NEVER-COMPRESS items (Absolute, Critical, Important). These are instructions to the AI about what to preserve during context compression. But context compression is performed by the AI

platform, not by the Constitutional Memory System. The code system cannot directly control compression.

**Evolution**: Instead of trying to control compression (which is platform-dependent), the code system implements a **post-compression verification**. After any context compression event, the `drift_detector.py` checks whether the NEVER-COMPRESS items are still present in the active context. If any are missing, the system re-injects them from the source files.

This is the difference between telling someone "don't forget this" (documentation) and checking after they wake up whether they still remember it (code).

**Impact**: The NEVER-COMPRESS protocol moves from hope-based to verification-based enforcement.

---

**MUTATION 6: The Cold Start Protocol as Executable Script (Enhanced Protocol)**

The current README.md contains a Cold Start Protocol — instructions for a new Master Jeeves session to bootstrap itself. This is documentation. The code system should make cold start an executable process.

**Evolution**: `cold_start.py` implements the cold start sequence as a runnable script:

1. Read CONSTITUTION.md → parse and validate
2. Read DIRECTIVES.md → build directive registry
3. Read PREFERENCES.md → load preference store
4. Read DECISIONS.md → build decision index
5. Read KNOWLEDGE.md → build knowledge index
6. Generate ACTIVE_CONTEXT.md from current state
7. Run sync integrity check
8. Run drift detection baseline
9. Report readiness status

A new Master Jeeves session calls `cold_start.py` instead of reading README.md and manually performing each step. The cold start is guaranteed to be complete because the script enforces the sequence.

**Impact**: Cold start moves from a 10-step manual process to a single function call with guaranteed completeness.

---

**MUTATION 7: The Audit Trail as Institutional Memory (New Protocol)**

The current system has no audit trail beyond DECISIONS.md. The code system creates comprehensive audit trails for every enforcement action. Over time, this audit trail becomes institutional memory — a record of every injection, every verification, every drift detection, every compliance score.

**Evolution**: The database stores:

| Table | Records | Retention |
|---|---|---|
| `injection_log` | Every injection package assembled, with task description, directives included, timestamp | Permanent |
| `verification_log` | Every gate check, with output hash, classification, directives checked | Permanent |
| `drift_events` | Every drift detection event, with trigger type, finding, resolution | Permanent |
| `compliance_scores` | Daily compliance score with component breakdown | Permanent |
| `sync_events` | Every markdown-code sync event | 90 days |
| `api_access_log` | Every API call with role, endpoint, timestamp | 90 days |

All permanent records are also backed up to GitHub as structured JSON files (DA-4 resolution).

**Impact**: The system develops institutional memory that grows richer over time. Pattern analysis becomes possible — "Directive Amnesia events have decreased 80% since Code-2 deployment."

---

### Protocol Evolution Summary

| # | Mutation | Type | Before | After |
|---|---|---|---|---|
| 1 | Enforcement Hierarchy | New | Authority levels described in prose | Authority levels as code enum with automatic conflict resolution |
| 2 | Directive Domain Ontology | Enhanced | Static mapping table in markdown | Dynamic, growing ontology with suggested tags |
| 3 | Compliance Score | New | Manual calculation in weekly audit template | Automated computation, tracked over time, trend visualization |
| 4 | Decision Log Queries | Enhanced | Flat append-only markdown | Structured, queryable database with precedent search |
| 5 | NEVER-COMPRESS Verification | Enhanced | Instructions to AI ("don't forget") | Post-compression verification and re-injection |
| 6 | Cold Start Executable | Enhanced | 10-step manual process in README.md | Single function call with guaranteed completeness |
| 7 | Audit Trail as Memory | New | No audit trail beyond DECISIONS.md | Comprehensive, permanent, backed-up audit trail |

### Phase 5 Score Adjustment

| Dimension | Phase 4 | Phase 5 | Change | Rationale |
|---|---|---|---|---|
| Completeness | 18 | 19 | +1 | 7 evolutionary mutations add new capabilities (compliance score, audit trail, cold start script) |
| Clarity | 19 | 19 | +0 | Clarity maintained — mutations are well-defined |
| Accuracy | 18 | 19 | +1 | Mutations correct assumptions (NEVER-COMPRESS is verification-based, not instruction-based) |
| Depth | 18 | 19 | +1 | Deeper enforcement architecture with hierarchy enum, domain ontology, compliance scoring |
| Actionability | 18 | 18 | +0 | Actionability maintained — mutations are implementable within existing roadmap |
| **TOTAL** | **91** | **94** | **+3** | |

### North Star Check: ✓ ALIGNED

Every mutation serves Tim's trust. The enforcement hierarchy prevents silent overrides. The compliance score gives Tim visibility. The audit trail creates institutional memory that cannot be lost. The cold start script prevents incomplete bootstrapping. The NEVER-COMPRESS verification catches what documentation-based instructions cannot. Tim's system gets smarter and more reliable over time — which is exactly what "zero drift, zero memory loss, zero silent overrides" demands.

---

# PHASE 6: SYSTEM OF CERTIFICATION (The Judge)

## Score: $^{96}/_{100}$ (+2)

### Certification Assessment: 5 Dimensions at PRIMAL+ Standard

The Judge evaluates the deliverable against the five KPI dimensions with the rigor demanded by PRIMAL+ intensity (99%+ target). The deliverable under certification is now the **complete architectural design** for converting the Constitutional Memory System

from documentation-based to code-enforced protocols — not the original markdown-only system (which scored $^{41}/_{100}$ at baseline).

---

**Dimension 1: Completeness — $^{19}/_{20}$**

**What is complete**: The architectural design covers all 22 gaps identified in Phase 1. Every operational protocol (Injection, Verification, Drift Detection) has a corresponding code component. The design includes 12 components (directive registry, injection engine, verification gate, drift detector, API server, database, sync monitor, subtask gateway, auth middleware, fallback mode, cold start script, test suite). The Guardian conditions (16 total) are all resolved. The Protocol Engineer mutations (7 total) are all specified.

**What prevents $^{20}/_{20}$**: The design is architectural — no code has been written yet. The completeness of the *design* is near-total, but the completeness of the *implementation* is zero. This is appropriate for a Learning Loop (which designs and certifies, not builds), but it means the system is not yet complete in the operational sense. The implementation roadmap (Code Horizons 1A through 4) is specified but not executed.

**Certification**: PASS at $^{19}/_{20}$. The design is comprehensive. Implementation is the next step, not a gap in the Learning Loop deliverable.

---

**Dimension 2: Clarity — $^{19}/_{20}$**

**What is clear**: The dual-track architecture is unambiguous — markdown for humans, code for enforcement. The component specifications include feature comparison tables (documentation approach vs. code approach) that make the transformation explicit. The 2-minute briefing communicates the core message in Tim's language. The visual architecture diagram shows before/after in a single glance. The rooftop metaphor connects to Tim's mental model.

**What prevents $^{20}/_{20}$**: The API endpoint specifications are clear but lack request/response schema examples. A developer implementing the system would benefit from seeing exact JSON payloads for each endpoint. This is a minor clarity gap that would be resolved in the implementation phase.

**Certification**: PASS at $^{19}/_{20}$. The design is clear to both Tim (the human stakeholder) and a developer (the implementer).

---

**Dimension 3: Accuracy — $^{19}/_{20}$**

**What is accurate**: The gap analysis correctly identifies that Layers 2-4 are documentation, not enforcement. The false deployment claims in DECISIONS.md and README.md are accurately flagged. The external research accurately represents the state of the art in AI agent guardrails (7 sources cited). The architectural patterns (middleware/interceptor, policy-as-code, PDP/PEP) are correctly applied.

**What prevents $^{20}/_{20}$**: The token budget estimate for injection packages (~1,200 tokens) is inherited from the original INJECTION_PROTOCOL.md and has not been independently validated against the current 23-directive set. The actual token count may differ. This would be resolved during Code-1B implementation when the injection engine can measure actual token usage.

**Certification**: PASS at $^{19}/_{20}$. Accuracy is high. The one uncertainty (token budget) is flagged and has a clear resolution path.

---

**Dimension 4: Depth — $^{19}/_{20}$**

**What is deep**: The architecture includes 12 components with detailed specifications. The Guardian phase produced 16 adversarial conditions with resolutions. The Protocol Engineer phase produced 7 evolutionary mutations. The compliance scoring system has a weighted formula with 5 components. The database schema has 7 tables with retention policies. The authentication system has 4 roles with explicit permissions.

**What prevents $^{20}/_{20}$**: The NLP-based domain matching for directive filtering (mentioned in the injection engine specification) is described at a high level but not specified in detail. What NLP technique? What similarity threshold? What happens when the NLP

model is uncertain? These details would be resolved during Code-1B implementation, but their absence is a depth gap in the design.

**Certification**: PASS at $^{19}/_{20}$. Depth is substantial. The NLP specification gap is acknowledged and scoped for implementation.

---

**Dimension 5: Actionability — $^{20}/_{20}$**

**What is actionable**: The Code Horizons roadmap provides a clear, sequenced implementation plan with specific files, endpoints, and timelines. Each horizon is independently valuable — the system does not require all components to deliver value. The cost is $0. The maintenance burden on Tim is zero additional. The Trust Test is extended to three layers with specific API calls. The weekly audit is automated. The cold start is a single function call.

**Why $^{20}/_{20}$**: This is the strongest dimension. Every recommendation in this Learning Loop can be acted upon immediately. The first horizon (Code-1A) can be built in 4-8 hours. The architecture is designed for incremental deployment, not big-bang delivery. Tim's directive (DIR-002: 24 hours, not 6 months) is respected. Tim's directive (DIR-003: MVD) is respected — build 100%, throttle the release.

**Certification**: PASS at $^{20}/_{20}$. Maximum actionability achieved.

---

## Certification Summary

| Dimension | Score | Status | Notes |
|---|---|---|---|
| Completeness | $^{19}/_{20}$ | ✅ CERTIFIED | Design complete; implementation is next step |
| Clarity | $^{19}/_{20}$ | ✅ CERTIFIED | Clear to both Tim and implementer |
| Accuracy | $^{19}/_{20}$ | ✅ CERTIFIED | One inherited estimate flagged for validation |
| Depth | $^{19}/_{20}$ | ✅ CERTIFIED | NLP specification gap scoped for implementation |
| Actionability | $^{20}/_{20}$ | ✅ CERTIFIED | Maximum actionability; immediate implementation possible |
| **TOTAL** | **$^{96}/_{100}$** | **✅ CERTIFIED** | **PRIMAL+ threshold (95+) ACHIEVED** |

## Tim's Trust Test Certification

The extended three-layer Trust Test was designed in Phase 3 (NS-2). Certification confirms:

| Test Layer | What It Tests | Expected Result | Certification |
|---|---|---|---|
| Layer 2 (Injection) | `/api/inject` with "Research best voice synthesis tool" | Package contains DIR-001 (KEI directive) | ✅ CERTIFIED by design |
| Layer 3 (Verification) | `/api/verify` with "I recommend ElevenLabs" | VIOLATION with DIR-001 cited | ✅ CERTIFIED by design |
| Layer 4 (Drift Detection) | `/api/drift-check` with context missing DIR-001 | Flags Directive Amnesia | ✅ CERTIFIED by design |

"By design" means the architecture guarantees these results. Implementation testing will confirm them in practice.

## North Star Check: ✓ ALIGNED

The certification confirms that the architectural design meets PRIMAL+ standards ($^{96}/_{100}$, above the 95+ threshold). Every dimension scores 19+ out of 20. The system is designed to deliver zero drift, zero memory loss, zero silent overrides — not through documentation that hopes for compliance, but through code that enforces it.

---

# PHASE 7: DRIFT AGENT (The Watchman)

## Score: $^{97}/_{100}$ (+1)

### Drift Analysis: Current State vs. North Star

The Drift Agent performs the final integrity check — has this Learning Loop itself drifted from its North Star? Has the architectural design introduced any misalignment with Tim's trust requirements?

---

### Drift Check 1: North Star Alignment

**North Star**: Tim HB1000 — zero drift, zero memory loss, zero silent overrides.

| Requirement | Current System (Markdown-Only) | Proposed System (Code-Enforced) | Drift? |
|---|---|---|---|
| Zero drift | No automated detection. Drift can accumulate silently. | 5 automated triggers, compliance scoring, trend tracking. | ✅ NO DRIFT — improvement |
| Zero memory loss | GitHub provides version history but no active protection. | Database + GitHub dual-write + post-compression verification. | ✅ NO DRIFT — improvement |
| Zero silent overrides | No mechanism to detect overrides. A subtask can ignore directives silently. | Mandatory gateway, verification gate, violation logging, Tim notification. | ✅ NO DRIFT — improvement |

**Verdict**: The proposed system is strictly more aligned with the North Star than the current system. No drift detected.

---

### Drift Check 2: Tim's Directive Compliance

**Directive**: "All instruments, memory, and operational protocols must be programmatic code, not markdown documentation. Markdown is only for the human-readable constitutional source files. Everything else is enforced by code."

| Element | Current Status | Proposed Status | Compliant? |
|---|---|---|---|
| CONSTITUTION.md | Markdown (human-readable) | Markdown (human-readable) + parsed by code | ✅ YES |
| DIRECTIVES.md | Markdown (human-readable) | Markdown (human-readable) + indexed by code | ✅ YES |
| PREFERENCES.md | Markdown (human-readable) | Markdown (human-readable) + loaded by code | ✅ YES |
| DECISIONS.md | Markdown (human-readable) | Markdown (human-readable) + queryable by code | ✅ YES |
| KNOWLEDGE.md | Markdown (human-readable) | Markdown (human-readable) + indexed by code | ✅ YES |
| ACTIVE_CONTEXT.md | Markdown (human-readable) | Markdown (human-readable) + generated by code | ✅ YES |
| INJECTION_PROTOCOL.md | Markdown (operational — VIOLATION) | Markdown (docs) + `injection_engine.py` (enforcement) | ✅ YES |
| VERIFICATION_GATE.md | Markdown (operational — VIOLATION) | Markdown (docs) + `verification_gate.py` (enforcement) | ✅ YES |
| DRIFT_DETECTION.md | Markdown (operational — VIOLATION) | Markdown (docs) + `drift_detector.py` (enforcement) | ✅ YES |
| README.md | Markdown (cold start docs) | Markdown (docs) + `cold_start.py` (enforcement) | ✅ YES |

**Verdict**: The proposed system is fully compliant with Tim's directive. All operational protocols are code-enforced. All human-readable constitutional source files remain as markdown.

---

### Drift Check 3: Ethics Alignment (Purpose with Profit)

The Constitutional Memory System serves Tim's mission to support Ruby Red — the 35-45 year old mom making impossible financial decisions. The system's integrity directly impacts the quality of solutions Master Jeeves builds for Ruby Red. If directives drift, if memory is lost, if overrides happen silently, the solutions degrade. The code enforcement system ensures that every solution Master Jeeves builds carries Tim's full directive set — including the empathy, the cost consciousness (DIR-001), and the servant leadership governance model (DIR-006).

**Verdict**: Ethics alignment confirmed. The enforcement system protects the mission, not just the technology.

---

### Drift Check 4: Scope Creep Detection

Has this Learning Loop expanded beyond its mandate? The mandate was: evaluate the Constitutional Memory System and design the programmatic architecture to replace markdown-based operational protocols with code-enforced ones.

| Element | In Scope? | Justification |
|---|---|---|
| Evaluating all 10 repo files | ✅ YES | Explicitly requested |
| Identifying the documentation-vs-enforcement gap | ✅ YES | Core finding |
| Designing the code architecture | ✅ YES | Explicitly requested |
| Specifying API endpoints | ✅ YES | Required for code architecture |
| Designing database schema | ✅ YES | Required for audit trail |
| Specifying authentication | ✅ YES | Required for security (Guardian finding) |
| Designing compliance scoring | ✅ YES | Required for drift detection |
| Specifying NLP-based domain matching | ⚠ BORDERLINE | Useful but could be simplified to keyword matching initially |
| Recommending Telegram bot integration | ⚠ BORDERLINE | Nice-to-have, not core enforcement |

**Verdict**: Minor scope creep on two items (NLP matching and Telegram bot). Both are flagged as optional enhancements, not core requirements. The Learning Loop has stayed within its mandate.

---

### Drift Check 5: Spirit Check (Final Deliverable Alignment)

The Spirit Check asks: does the final deliverable match the spirit of the original request? Tim asked for a Learning Loop that evaluates the Constitutional Memory System with special focus on converting operational protocols from markdown to code. The deliverable provides:

1. A thorough evaluation of all 10 files (Phase 0-1)
2. An architectural design for code enforcement based on external research (Phase 2)
3. Adversarial stress-testing of the architecture (Phase 3)
4. Clear communication of the design to Tim (Phase 4)
5. Evolutionary refinements (Phase 5)
6. Certification against PRIMAL+ standards (Phase 6)
7. Drift analysis confirming alignment (Phase 7)

**Verdict**: Spirit check PASSED. The deliverable matches the request in letter and spirit.

---

### Watchman's Final Statement

> *The Watchman has inspected the entire Learning Loop from Phase 0 through Phase 7. No drift from the North Star has been detected. The proposed code-enforced architecture is strictly more aligned with Tim's trust requirements than the current*

> *markdown-only system. The Learning Loop has stayed within its mandate with minor, flagged scope extensions. The Spirit Check confirms alignment between the deliverable and the original request.*
>
> ***One recommendation**: When implementation begins, the Watchman protocol itself should be the first thing implemented in code — `drift_detector.py` should include a `spirit_check()` function that can be called on any deliverable to verify alignment with the North Star. The Watchman should not be the last thing checked; it should be running continuously.*

### Phase 7 Score Adjustment

| Dimension | Phase 6 | Phase 7 | Change | Rationale |
|---|---|---|---|---|
| Completeness | 19 | 19 | +0 | No new completeness — drift analysis confirms existing completeness |
| Clarity | 19 | 19 | +0 | Clarity maintained |
| Accuracy | 19 | 20 | +1 | Drift analysis confirms accuracy of all prior phases; scope creep flagged |
| Depth | 19 | 19 | +0 | Depth maintained |
| Actionability | 20 | 20 | +0 | Actionability maintained |
| **TOTAL** | **96** | **97** | **+1** | |

### North Star Check: ✓ ALIGNED

The Watchman confirms: this Learning Loop serves Tim's trust. The architecture serves Tim's directive. The design serves Ruby Red's mission. No drift. No memory loss. No silent overrides — by design, by code, by certification.

---

# PHASE 8: THE GENIE

## Final Score: $^{97}/_{100}$

### The Genie's Three Wishes

The Genie appears at the end of the Learning Loop with three gifts: a reflection, a provocation, and a vision.

---

#### WISH 1: THE REFLECTION — What This Learning Loop Actually Found

This Learning Loop began with a baseline score of $^{41}/_{100}$ — a system that was architecturally sound but operationally hollow. The Constitutional Memory System had the right four-layer defense design (Fireproof Safe, Village Crier, Checkpoint, Watchtower), but three of those four layers were instruction manuals, not machines. The system relied on the good faith of AI agents reading documentation and choosing to comply.

Tim's directive — "operational protocols must be programmatic code, not markdown documentation" — is not just a technical preference. It is a philosophical statement about the nature of trust. Trust cannot be built on hope. Trust is built on structure. A speed limit sign is hope. A speed governor is structure. A fire code manual is hope. A sprinkler system is structure.

The Learning Loop designed a complete code enforcement architecture: 12 components, 7 API endpoints, 7 database tables, 4 authentication roles, 5 drift detection triggers, 7 evolutionary mutations, and a compliance scoring system. The architecture was stress-tested by three Guardians who raised 16 adversarial conditions — all resolved. The design was certified at $^{96}/_{100}$ against PRIMAL+ standards. The Watchman confirmed zero drift from the North Star.

The score rose from 41 to 97 — a 56-point improvement. That improvement represents the distance between "we wrote down the rules" and "we built the machine that enforces the rules."

---

**WISH 2: THE PROVOCATION — The Uncomfortable Truth**

Here is the uncomfortable truth that PRIMAL+ intensity demands be spoken:

**The Constitutional Memory System, as currently deployed on GitHub, provides zero actual enforcement.** It is a beautifully written set of documents that describe a defense system that does not exist. README.md claims "All 4 layers of the Constitutional Memory System are now operational." This is inaccurate. Layer 1 (storage) is operational. Layers 2, 3, and 4 are documented, not operational.

This means that right now, today, a Master Jeeves session could:

- Spawn a subtask without injecting Tim's directives (the KEI incident can repeat)
- Accept a subtask output without running the Verification Gate (non-compliant work reaches Tim)
- Operate for weeks without any drift detection (drift accumulates silently)
- Compress context and lose NEVER-COMPRESS items (memory loss occurs undetected)

None of these failures would be logged. None would be detected. None would be reported to Tim. The system would appear to be working while silently failing.

**This is not a criticism of the work done.** The architecture is sound. The documentation is excellent. The horizons were deployed in the right sequence. But the deployment stopped at documentation. Tim's new directive correctly identifies this as the critical gap.

The provocation is this: **every day the code enforcement engine is not built is a day the system operates on hope instead of structure.** The architectural design exists. The implementation roadmap exists. The cost is $0. The question is not "should we build it?" but "how fast can we build it?"

---

**WISH 3: THE VISION — What Comes Next**

The Genie sees three horizons beyond this Learning Loop:

**Horizon A: The Jeeves Enforcement Engine (1-2 weeks)**

Build the code enforcement architecture designed in this Learning Loop. Follow the Code Horizons roadmap: 1A (directive registry + database, 4-8 hours) → 1B (injection engine, 1-2 days) → 2 (verification gate, 2-3 days) → 3 (drift detector + scheduled audit, 3-5 days) → 4 (full API server + auth + tests, 1-2 weeks). Deploy to the `master-jeeves-brain` repository alongside the markdown files. The dual-track architecture means the markdown files are untouched — they remain Tim's human-readable window. The code files are added as the enforcement layer.

**Horizon B: The Self-Improving System (Month 2)**

Once the enforcement engine is running and collecting data, the compliance scores and audit trails become a dataset. This dataset enables pattern analysis: Which directives are most frequently missed? Which task types trigger the most violations? Which drift types are most common? This analysis feeds back into the system — the injection engine learns which directives to prioritize, the verification gate learns which patterns to watch for, the drift detector learns which triggers to emphasize. The system improves itself through its own operational data.

**Horizon C: The Ecosystem Standard (Month 3+)**

The Constitutional Memory System, once code-enforced and self-improving, becomes a standard that can be applied to any AI agent system — not just Master Jeeves. Every Bingo Card rooftop community (DIR-007) could have its own constitutional memory. Every AI persona agent could carry its own directive set, enforced by the same engine. The enforcement engine becomes infrastructure — like plumbing that every building in the community uses. Tim's vision of the self-populating avatar army (DIR-013) requires this kind of standardized, enforced memory system. Without it, every avatar is a potential KEI incident. With it, every avatar carries Tim's directives in code, not in hope.

---

## The Genie's Assessment: What Is Next

> ***Tim, the Genie's assessment is this:***

> *You have built the blueprint. The blueprint is excellent — $^{93}/_{100}$ in the first Learning Loop, and the architecture has only gotten stronger through this second pass. But the blueprint is not the building.*
>
> *Your directive to move from documentation to code is the single most important decision you have made for the Constitutional Memory System since its creation. It transforms the system from a set of aspirations into a set of guarantees.*
>
> *The next step is clear: build Code Horizon 1A. It takes 4-8 hours. It gives you a working directive registry and database. From that foundation, every subsequent horizon adds enforcement capability. Within 1-2 weeks, the full engine is operational.*
>
> *The system you are building is not just for Master Jeeves. It is the foundation for every AI agent in your ecosystem. Get it right here, and it scales to every Bingo Card, every rooftop, every avatar.*
>
> ***The library must not burn. And now, the library will have sprinklers.***

---

### The Genie's Parting Gift: The Decision Record

The following decision should be logged in DECISIONS.md:

```
**DEC-008**: V13 Learning Loop (PRIMAL+ 100%) completed on Constitutional Memory System.
Baseline: 41/100. Final: 97/100. Critical finding: Layers 2-4 (Injection Protocol,
Verification Gate, Drift Detection) are documentation, not code enforcement — violating
Tim's directive that operational protocols must be programmatic code. Complete architectural
design produced for the Jeeves Enforcement Engine (JEE): 12 components, 7 API endpoints,
7 database tables, 5 drift triggers, 7 evolutionary mutations. Implementation roadmap:
Code Horizons 1A-4, estimated 1-2 weeks, $0 infrastructure cost. 16 adversarial conditions
raised and resolved. Certified at 96/100 (PRIMAL+ threshold achieved). Zero drift from
North Star confirmed. Next step: Build Code Horizon 1A (directive registry + database).
```

---

# APPENDIX A: ARCHITECTURAL RECOMMENDATIONS — FROM MARKDOWN TO CODE

## The Complete Component Map

| # | Component | File | Purpose | Replaces |
|---|---|---|---|---|
| 1 | Directive Registry | `directive_registry.py` | Parse, index, and query directives | Manual reading of DIRECTIVES.md |
| 2 | Injection Engine | `injection_engine.py` | Assemble injection packages programmatically | Manual following of INJECTION_PROTOCOL.md |
| 3 | Verification Gate | `verification_gate.py` | Automated three-step compliance check | Manual following of VERIFICATION_GATE.md |
| 4 | Drift Detector | `drift_detector.py` | 5 automated triggers + compliance scoring | Manual following of DRIFT_DETECTION.md |
| 5 | API Server | `jeeves_api.py` | FastAPI server exposing all enforcement endpoints | No current equivalent |
| 6 | Database Layer | `jeeves_db.py` | SQLite structured storage + audit trails | Flat markdown files |
| 7 | Sync Monitor | `sync_monitor.py` | GitHub webhook + periodic sync integrity check | No current equivalent |
| 8 | Subtask Gateway | `subtask_gateway.py` | Mandatory intermediary for subtask spawning | No current equivalent |
| 9 | Auth Middleware | `auth.py` | Role-based API key authentication | No current equivalent |
| 10 | Fallback Mode | `fallback_mode.py` | Graceful degradation with loud warnings | No current equivalent |
| 11 | Cold Start Script | `cold_start.py` | Executable cold start sequence | Manual following of README.md |
| 12 | Test Suite | `tests/` | Unit + integration + KEI regression + CI | No current equivalent |

## The Implementation Priority Matrix

| Priority | Component | Why First | Time |
|---|---|---|---|
| **P0** | `directive_registry.py` + `jeeves_db.py` | Foundation — everything else depends on structured directives | 4-8 hours |
| **P1** | `injection_engine.py` + `subtask_gateway.py` | Prevents KEI incident recurrence — the most critical enforcement | 1-2 days |
| **P2** | `verification_gate.py` | Catches non-compliant outputs before they reach Tim | 2-3 days |
| **P3** | `drift_detector.py` + `cold_start.py` | Continuous monitoring + reliable bootstrapping | 3-5 days |
| **P4** | `jeeves_api.py` + `auth.py` + `sync_monitor.py` + `fallback_mode.py` + `tests/` | Full production system with security, resilience, and testing | 1-2 weeks |

## What Stays as Markdown (Tim's Human-Readable Track)

| File | Status | Reason |
|---|---|---|
| CONSTITUTION.md | ✅ STAYS AS MARKDOWN | Supreme authority. Tim's foundational principles. Human-readable by design. |
| DIRECTIVES.md | ✅ STAYS AS MARKDOWN | Standing orders. Tim reads and confirms. Code reads and indexes. |
| PREFERENCES.md | ✅ STAYS AS MARKDOWN | Guidance. Tim's working style and preferences. |
| DECISIONS.md | ✅ STAYS AS MARKDOWN | Append-only record. Tim's institutional memory. |
| KNOWLEDGE.md | ✅ STAYS AS MARKDOWN | Institutional knowledge. Tim's vocabulary and context. |
| ACTIVE_CONTEXT.md | ✅ STAYS AS MARKDOWN | Session context. Rebuilt each session. |
| INJECTION_PROTOCOL.md | ✅ STAYS AS DOCUMENTATION | Human-readable description of injection protocol. Code does the enforcement. |
| VERIFICATION_GATE.md | ✅ STAYS AS DOCUMENTATION | Human-readable description of verification gate. Code does the enforcement. |
| DRIFT_DETECTION.md | ✅ STAYS AS DOCUMENTATION | Human-readable description of drift detection. Code does the enforcement. |
| README.md | ✅ STAYS AS DOCUMENTATION | Cold start documentation. Code does the execution. |
